Supervised Learning - Logistics Regression.

Predicting the risk of dying of heart disease.

The World Health Organization estimates 12 million people die annually due to heart disease. This model identifies the most significant heart disease risk variables and forecasts the overall risk.

Model	Accuracy (R^2)
Baseline	84.77%
Logistics Regression	86.02%

Supervised Learning - Linear Regression.

Predicting the price of Wine.

Wine prices were thought to be predicted well only by experts until Princeton professor Orley Ashenfelter proved otherwise. This model predicts wine prices.

Model	Accuracy (Adjusted R^2)
Multiple linear regression	79.40%

```
print (LinearRegModel.summary())
print(wine.corr())

wineTest = pd.read_csv("wineTest.csv")
print(wineTest.info())
# Predict
predictTest = LinearRegModel.predict(sm.ad

import numpy as np
# Compute R-Squared on the test
SSE = np.sum((predictTest - wineTest["Pric
SST = np.sum((wine["Price"].mean() - wineT
r2 = 1 - SSE / SST
```

Unsupervised Learning - Clustering.

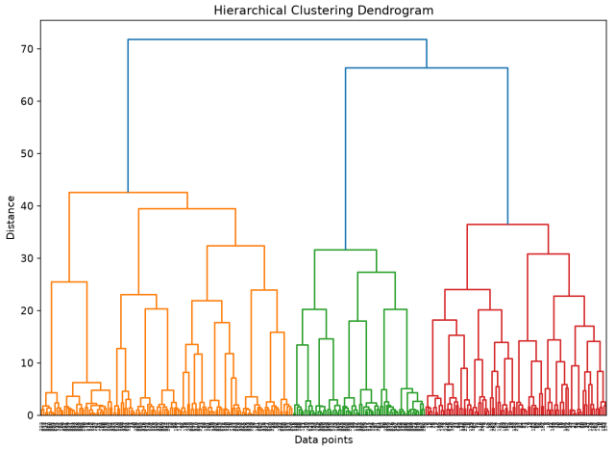

Understand the risk of heart failure profiles of patients.

64 million people worldwide live with heart failure at a given time[1]. This model helps us understand which factors lead to a heart failure risk by grouping patients.

Model	Accuracy
CART	86.28%

Four clusters of patients according to their risk of heart failure:

- Highest: patients with high blood pressure and diabetes.
- High: patients without high blood pressure but at risk as they smoke.
- Moderate: patients with high blood pressure but without diabetes.
- Low: healthier patients, without high blood pressure and without diabetes.
